
Histograms: the null. 100 random splits of the 267 patients into a pseudo-A7 of 65 and a pseudo-A9 of 202, rebuilding the subsamples, the networks and the metrics each time. Vertical lines: the observed statistic. The split keeps the patient-overlap structure of the real design and destroys only clade identity, so a line inside its own histogram means the intra–inter gap is what the subsampling produces by itself. P = 0.0099 is the floor: 0 of 100 permutations.
